LOCAL UTILITY AND MULTIVARIATE RISK AVersion

ARTHUR CHARPENTIER, ALFRED GALICHON, AND MARC HENRY

Abstract. We revisit Machina’s local utility as a tool to analyze attitudes to multivariate risks. Using martingale embedding techniques, we show that for non-expected utility maximizers choosing between multivariate prospects, aversion to multivariate mean preserving increases in risk is equivalent to the concavity of the local utility functions, thereby generalizing Machina’s result in [18]. To analyze comparative risk attitudes within the multivariate extension of rank dependent expected utility of [10], we extend Quiggin’s monotone mean and utility preserving increases in risk and show that the useful characterization given in [17] still holds in the multivariate case.

Keywords: local utility, multivariate risk aversion, multivariate rank dependent utility, pessimism, multivariate Bickel-Lehmann dispersion.

JEL subject classification: D63, D81, C61

Introduction

One of the many appealing features of expected utility theory is the characterization of attitudes towards risk through the shape of the utility function. Following extensive evidence of violations of the independence axiom which delivers linearity in probabilities of the functional characterizing preferences over risky prospects, most notably the celebrated Allais paradox [1], Machina showed in [18], [19] that smoothness of the preference functional was sufficient to recover representability of risk attitudes through a local approximation, which he dubbed local utility function. Parallel to the study of risk attitudes in generalized expected utility theories, [28] and [16] analyzed attitudes to the combination of income risk and price risk in preferences over multiple commodities within the expected utility framework. This paper is concerned with non expected utility analysis of attitudes to multivariate risks. So far,
three approaches have emerged to analyze attitudes to multivariate risks without the
independence axiom in [31], [24] and [12]. All three apply dimension reduction devices
to preferences over multivariate prospects. [31] considers rank dependent utility over
multivariate prospects with stochastically independent components only; [24] show
additive separability of the local utility function under a property they call dominance
(equivalent to the notion of correlation neutrality in [9]) and [12] show that under a
property they call degenerate independence, preferences over uncertain multivariate
prospects can be fully recovered from preferences over uncertain income and prefer-
ences over deterministic multivariate outcomes. We consider the general case, where
attitudes to income risk and price risk cannot be separated in this way and show that
in general smooth preferences over multivariate prospects, the main result of [18] still
holds, and aversion to increases in risk is equivalent to concavity of the local utility
function. The proof relies on the martingale characterization of increasing risk in
[10] and martingale embedding theory, specifically [14]. A special case of this result
appears in [10], who derive the family of local utility functions in a multivariate rank
dependent utility model under aversion to multivariate mean preserving increases in
risk. Machina also showed in [18] that interpersonal comparisons of risk aversion can
be characterized by properties of the local utility function. Karni generalizes in [15]
the equivalence between decreasing certainty equivalents and concave transformations
of the local utility functions to smooth preferences over multivariate prospects. To
complement this result, we extend the notion of compensated spread to multivariate
prospects and generalize the characterization of Quiggin’s monotone increases in risk
[21] as mean preserving comonotonic spreads in [17]. We also generalize Quiggin’s
notion of pessimism and characterize pessimistic decision functionals by the shape of
their local utility function. We apply these notions to interpersonal comparison of
risk aversion within the multivariate rank dependent model of [10] and we show that
pessimism is equivalent to weak risk aversion in that framework.

The rest of the paper is organized as follows. Section 1 defines local utility. Section 2
shows that aversion to mean preserving increases in risk is equivalent to concavity of
the local utility functions and Section 3 extends Quiggin’s monotone mean preserving
increases in risk and applies it to interpersonal comparisons of risk aversion within
the multivariate rank dependent utility model. The last section concludes.

Notation and basic definitions. Let \((S, \mathcal{F}, \mathbb{P})\) be a non-atomic probability space.
Let \(X : S \to \mathbb{R}^d\) be a random vector. We denote the cumulative distribution function
of \(X\) by \(F_X\). \(\mathbb{E}\) is the expectation operator with respect to \(\mathbb{P}\). For \(x\) and \(y\) in \(\mathbb{R}^d\), let
\(x \cdot y\) be the standard scalar product of \(x\) and \(y\), and \(\|x\|^2\) the Euclidian norm of \(x\). We
denote by \(X =_d \mu\) the fact that the distribution of \(X\) is \(\mu\) and by \(X =_d Y\) the fact that
\(X\) and \(Y\) have the same distribution. \(Q_X\) denotes the quantile function of distribution \(X\). In dimension 1, this is defined for all \(t \in [0, 1]\) by
\[Q_X(t) = \inf_{x \in \mathbb{R}} \{\Pr(X \leq x) > t\}.\]
In larger dimensions, it is defined in Definition 5 of Section 3.2 below. We call \(L^2_d\) the
set of random vectors \(X\) in dimension \(d\) such that \(\mathbb{E} \|X\|^2 < \infty\). We denote by \(\mathcal{D}\) the
subset of \(L^2_d\) containing random vectors with a density relative to Lebesgue measure.
A functional \(\Phi\) on \(L^2_d\) is called upper semi-continuous (denoted u.s.c.) if for any real
number \(\alpha\), \(\{X \in L^2_d : \Phi(X) > \alpha\}\) is open. A functional \(\Phi\) is lower semi-continuous
(l.s.c.) if \(-\Phi\) is upper semi-continuous. \(\Phi\) is called law-invariant if \(\Phi(X) = \Phi(\tilde{X})\)
whenever \(\tilde{X} =_d X\). By a slight abuse of notation, when \(\Phi\) is law invariant, \(\Phi(F_X)\) will
be used to denote \(\Phi(X)\). For a convex lower semi-continuous function \(V : \mathbb{R}^d \to \mathbb{R}\),
we denote by \(\nabla V\) its gradient (equal to the vector of partial derivatives).

1. Local Utility

We consider decision makers choosing among multivariate uncertain prospects \(X \in \mathcal{D}\). We assume that the decision makers’ preferences over \(\mathcal{D}\) are given as a complete,
reflexive and transitive binary relation represented by a real valued functional \(\Phi\),
which is continuous relative to the topology of convergence in distribution. We further
assume that \(\Phi\) is law-invariant. For a given prospect distribution \(F\), if there exists a
function \(U(x; F)\) such that
\[\Phi(F^*) - \Phi(F) - \int U(x; F)[dF^*(x) - dF(x)] \to 0\]
when $F^*$ converges to $F$ in distribution, then $U(x; F)$ is called local utility function relative to $\Phi$ at $F$. Since expected utility preferences are linear in probabilities, the local utility of an expected utility decision maker is constant and equal to her utility function. Theorem 1 in [18] shows that smooth preference functionals are monotonic if and only if their local utility functions are increasing. This can be extended to the case of multivariate prospects.

**Definition 1.** A prospect $X \in \mathcal{D}$ is said to dominate stochastically a prospect $Y$ (denoted $X \geq_{SD} Y$) if there exist $\tilde{X} =_d X$ and $\tilde{Y} =_d Y$ such that $\tilde{X} \geq \tilde{Y}$ almost surely, where $\geq$ denotes componentwise order in $\mathbb{R}^n$.

A preference functional is said to preserve stochastic dominance if stochastically dominant prospects are always preferred. If the preference functional $\Phi$ is law invariant and monotonic, in the sense that $\Phi(X) \geq \Phi(Y)$ when $X$ yields larger outcomes than $Y$ in almost all states, then it preserves stochastic dominance. Then we have the rather straightforward multivariate generalization of Theorem 1 of [18] (mentioned without proof in [24]).

**Proposition 1 (Monotonicity).** Let $\Phi$ be a law invariant preference functional, which admits a local utility $U(x; F)$ for all $F$. Then the following statements are equivalent. (i) $\Phi$ is monotone, i.e., $\Phi(X) \geq \Phi(Y)$ when $X \geq Y$ a.s., (ii) $\Phi$ preserves stochastic dominance and (iii) $U(x; F)$ is nondecreasing in $x$ for all $F$.

**Proof of Proposition 1.** Take any two multivariate prospects $X_1$ and $X_0$ such that $X_0 \leq X_1$ almost surely, where the inequality is component-wise. Define $X_t = tX_1 + (1-t)X_0$. A law invariant preference functional is increasing with respect to first order stochastic dominance if and only if it is monotone, i.e., if $\Phi(X_t)$ is a non decreasing function of $t$. Denote by $U_\Phi(\cdot; F_X)$ the local utility function of $\Phi$ at $F_X$. We have the
following:

\[
\frac{d}{dt} \Phi(X_t) = \frac{d}{dt} \Phi(tX_1 + (1-t)X_0) = \mathbb{E} \left[ \nabla U_\Phi(X_t, F_{X_1}) \cdot \frac{dX_1}{dt} \right] = \mathbb{E} \left[ \nabla U_\Phi(X_t, F_{X_1}) \cdot (X_1 - X_0) \right].
\]

Hence \( \Phi \) is monotone if and only if \( \nabla U_\Phi(\cdot; F_{X_1}) \geq 0 \) for all \( F_{X_1} \), which completes the proof. \( \square \)

If in addition, the decision maker is indifferent to correlation increasing transfers, or correlation neutral according to the terminology of [9], then Safra and Segal show in [24] that the local utility functions are additively separable, namely that \( U(x; F) = \sum_{j=1}^n U_j(x_j; F) \), where \( x_j \) is the \( j \)-th component of the outcome \( x \in \mathbb{R}^n \). Yaari’s rank dependent utility maximizers over stochastically independent \( d \)-dimensional risks in [31] are represented by

\[
\Phi(X) = \sum_{i=1}^d \alpha_i \int_0^1 \phi_i(u)Q_{X_i}(t)dt, \quad (1.1)
\]

where \( Q_{X_i} \) is the quantile function of component \( X_i \) of the risk \( X \), the \( \phi_i \)'s, \( i = 1, \ldots, d \), are non-negative functions on \([0,1]\) (quantile weights interpreted as probability distortions) and the \( \alpha_i \)'s, \( i = 1, \ldots, d \), are positive weights. The local utility of decision maker \( \Phi \) is given by

\[
U(x; F) = \sum_{i=1}^d \alpha_i \int_{x_i}^1 \phi(1 - F_i(z))dz, \quad (1.2)
\]

where \( F_i \) is the \( i \)-th marginal of distribution \( F \) (see for instance Section 4 of [26]).

2. Risk aversion

We now show that attitude to risk with smooth preference over multivariate prospects can be characterized by the shape of local utilities, as was proved in the case of univariate risks in Theorem 2 of [18]. The latter shows that aversion to mean preserving increases in risk is equivalent to concavity of local utility functions. Extending this
result to preferences over multivariate prospects calls for a generalization of the notion of mean preserving increase in risk proposed in [23].

**Definition 2** (Mean preserving increase in risk). A prospect $Y \in \mathcal{D}$ is called a mean preserving increase in risk (hereafter MPIR) of a prospect $X \in \mathcal{D}$, denoted $X \succ_{\text{MPIR}} Y$, if any of the following equivalent statements hold.

(a) For all bounded concave functions $f$ on $\mathbb{R}^n$, $\mathbb{E} f(X) \geq \mathbb{E} f(Y)$.

(b) There exists $\tilde{Y} =_{d} Y$ such that $(X, \tilde{Y})$ is a martingale, i.e., $\mathbb{E}[\tilde{Y}|X] = X$.

(c) For all u.s.c. law invariant concave functionals $\Psi$ on $\mathcal{D}$, $\Psi(X) \geq \Psi(Y)$.

The equivalence between (a) and (b) is due to [29] and the interpretation as an increase in risk is the same as in [23] for the univariate case. An immediate corollary of (c) (shown to be equivalent to (a) and (b) in [10]) is that cardinal risk aversion, i.e., concavity of the functional $\Phi$ representing preferences, implies ordinal risk aversion, in the sense of aversion to mean preserving increases in risk. We can now state the main result of this section, which is a direct generalization of Theorem 2 of [18].

**Theorem 1** (Risk aversion and local utility). Let $\Phi$ be a law invariant preference functional, which admits a local utility $U(x; F)$ for all $F$. Then the following statements are equivalent. (i) $\Phi$ is risk averse, i.e., $\Phi(X) \geq \Phi(Y)$ when $Y$ is an MPIR of $X$, (ii) $U(x; F)$ is a concave function of $x$ for all $F$ and (iii) $\Phi(\tilde{X}) \geq \Phi(X)$ whenever $\tilde{X}$ is a mixture of $F^*$ and $G_{\mu_F}$ and $X$ is an equally weighted mixture of $F^*$ and $F$, where $\mu_F$ is the mean of $F$ and $G_x$ is a degenerate distribution at $x$.

**Proof of Theorem 1.** In the following, we use the two alternative notations, $\Phi(X) = \Phi(F)$ where $X =_{d} F$, and the equivalent expression of the local utility equivalently, using the equivalence between the Gâteaux and the Fréchet derivative, when the latter exists: for all $H$,

$$U(\cdot, F) = \frac{\partial}{\partial \varepsilon} \Phi((1 - \varepsilon)F + \varepsilon H) \bigg|_{\varepsilon=0}.$$  

We denote $F^* = (1 - \varepsilon)F + \varepsilon H$.  

(i) \implies (ii): let \( Y \) be MPIR of \( X \), so that there exists \( \tilde{Y} =_{d} Y \) such that \((X, \tilde{Y})\) is a martingale, i.e., \( \mathbb{E}[\tilde{Y} | X] = X \) (from Definition 2). Then, following [14], there exists a continuous martingale \((\tilde{Y}_t, t \in [0, 1])\) such that \( \tilde{Y}_1 = \tilde{Y} \) and \( \tilde{Y}_0 = X \). More precisely, from Corollary 4.1.25 and Proposition 5.3.2 in [22], there exists \((\sigma_t)\) such that \( d\tilde{Y}_t = \sigma_t dB_t \) where \((B_t)\) is a standard \( d\)-dimensional Brownian motion, and \( \sigma_t = [\sigma_{i,j,t}]_{i,j=1,\ldots,d} \). Let \( F_t \) denote the distribution of \( \tilde{Y}_t \). From (i), since \((\tilde{Y}_t, t \in [0, 1])\) is a martingale, \( \Phi(\tilde{Y}_s) \geq \Phi(\tilde{Y}_t) \) if \( 0 \leq s \leq t \leq 1 \), or equivalently \( t \mapsto \Phi(F_t) \) is decreasing. Further, if \( dt > 0 \),

\[
\Phi(F_{t+dt}) - \Phi(F_t) = \mathbb{E}\left(U(\tilde{Y}_{t+dt}; F_{t+dt}) - U(\tilde{Y}_t; F_t)\right)
\]
i.e.,

\[
\Phi(F_{t+dt}) - \Phi(F_t) = \mathbb{E}\left(U(\tilde{Y}_{t+dt}; F_{t+dt}) - U(\tilde{Y}_t; F_t)\right) + \mathbb{E}\left[U(\tilde{Y}_{t+dt}; F_t) - U(\tilde{Y}_t; F_t)\right].
\]

For the second part, from Itô’s Lemma,

\[
U(\tilde{Y}_{t+dt}; F_t) - U(\tilde{Y}_t; F_t) = \int_t^{t+dt} \sum_{i=1}^d \frac{\partial U(\tilde{Y}_s; F_t)}{\partial y_i} d\tilde{Y}_i^s + \frac{1}{2} \sum_{i,j=1}^d \int_t^{t+dt} \frac{\partial^2 U(\tilde{Y}_s; F_t)}{\partial y_i y_j} d<\tilde{Y}_s, \tilde{Y}_s> \int_t^{t+dt} \sum_{i,j=1}^d \frac{\partial^2 U(\tilde{Y}_s; F_t)}{\partial y_i y_j} d<\tilde{Y}_s, \tilde{Y}_s>
\]

where \( d\tilde{Y}_s^i = \sum_{j=1}^d \sigma_{i,j,s} dB_t^j \), while \( d<\tilde{Y}_s^i, \tilde{Y}_s^j> = \sigma_{i,j,s}^2 \delta_{i,j} \sigma_s^2 ds \). If we take the expected value, the first part is zero, and therefore

\[
\mathbb{E}\left[U(X_{t+dt}; F_t) - U(X_t; F_t)\right] = \frac{1}{2} \sum_{i,j=1}^d \int_t^{t+dt} \frac{\partial^2 U(\tilde{Y}_s; F_t)}{\partial y_i y_j} \sigma_{s}^2 \delta_{i,j} \sigma_s^2 ds \]

Thus, if \( dt \downarrow 0 \),

\[
\mathbb{E}\left[U(X_{t+dt}; F_t) - U(X_t; F_t)\right] = \frac{1}{2} \mathbb{E}\left[\text{trace}(D^2 U(X_t; F_t)) \sigma_t \sigma_t^*\right] dt.
\]

Hence, since \( t \mapsto \Phi(F_t) \) is decreasing, it means that \( \mathbb{E}\left[\text{trace}(D^2 U(X_t; F_t)) \sigma_t \sigma_t^*\right] \leq 0 \). It follows that \( D^2 U(X_t; F_t) \) is a symmetric non-positive matrix, and so, \( x \mapsto U(x; F_t) \) is a concave function for all \( F_t \). In particular for \( t = 0 \). Q.E.D.

(ii) \implies (i): Suppose that \( x \mapsto U(x; F) \) is a concave function, for any distribution \( F \). Let \( X \) be a random variable with distribution \( F \), and consider \( Y \) such that \( Y \) is a MPIR of \( X \), i.e., there exists \( \tilde{Y} =_{d} Y \) such that \((X, \tilde{Y})\) is a martingale, i.e., \( \mathbb{E}[\tilde{Y} | X] = X \). As before, it is possible to interpolate from \( X \) to \( \tilde{Y} \) with a continuous
martingale \(\tilde{Y}_t\) on \([0, 1]\) with increments \(d\tilde{Y}_t = \sigma_t dB_t\). Using the same expressions we used earlier, we can derive that

\[
\Phi(F_{t+dt}) - \Phi(F_t) = \frac{1}{2} \mathbb{E} \left[ \text{trace}(D^2 U(X_t; F_t))\sigma_t \sigma_t^* \right] dt
\]

and since \(x \mapsto U(x; F)\) is a concave function, it follows that for all \(t\), \(\Phi(F_{t+dt}) - \Phi(F_t) \leq 0\), i.e. \(t \mapsto \Phi(F_t)\) is decreasing. And therefore \(\Phi(F_1) \leq \Phi(F_0)\), or equivalently \(\Phi(Y) = \Phi(\tilde{Y}) \leq \Phi(X)\). Q.E.D.

(ii) \(\Rightarrow\) (iii) Consider the following two lotteries, so that \(X = \alpha F + (1-\alpha)F^*\) and \(\tilde{X} = \alpha F + (1-\alpha)G_{\mu_F^*}\),

\[
X \quad \alpha F \quad \text{and} \quad \tilde{X} \quad \alpha F \quad (2.1)
\]

Given \(\varepsilon \in [0, 1]\), consider \(X_\varepsilon\) a mixture between \(X\) and \(\tilde{X}\), with weights \(\varepsilon\) and \(1-\varepsilon\), and let \(X_\varepsilon = d F_\varepsilon\),

\[
F_\varepsilon = \alpha F + (1-\alpha)[(1-\varepsilon)G_{\mu_F^*} + \varepsilon F^*]
\]

For \(h \geq 0\), note that

\[
F_{\varepsilon+h} = F_\varepsilon + (1-\alpha)h[F^* - G_{\mu_F^*}].
\]

If we substitute

\[
G_{\mu_F^*} = \frac{1}{(1-\alpha)(1-\varepsilon)}[F_\varepsilon - \alpha F - (1-\alpha)\varepsilon F^*]
\]

in equation (2.2), we get

\[
F_{\varepsilon+h} = \left[1 - \frac{h}{1-\varepsilon}\right] F_\varepsilon + \frac{h}{1-\varepsilon} [\alpha F + (1-\alpha)F^*],
\]

so that

\[
\Phi(F_{\varepsilon+h}) - \Phi(F_\varepsilon) = \Phi \left( \left[1 - \frac{h}{1-\varepsilon}\right] F_\varepsilon + \frac{h}{1-\varepsilon} [\alpha F + (1-\alpha)F^*] \right) - \Phi (F_\varepsilon).
\]

Let \(H = [\alpha F + (1-\alpha)F^*]\), so that this expression becomes

\[
\Phi((1-\eta)F_\varepsilon + \eta H) - \Phi (F_\varepsilon)
\]
with \( \eta = h/(1 - \varepsilon) \). Now,

\[
\Phi((1 - \eta)F_\varepsilon + \eta H) - \Phi(F_\varepsilon) = \int U(x; F_\varepsilon)d[(1 - \eta)F_\varepsilon + \eta H - F_\varepsilon] + o(h)
\]

\[
= \eta \int U(x; F_\varepsilon)d[\alpha F + (1 - \alpha)F^* - F_\varepsilon] + o(h)
\]

which equals

\[
\frac{h}{1 - \varepsilon} \left[ \int U(x; F_\varepsilon)d[\alpha F + (1 - \alpha)F^*] - \int U(x; F_\varepsilon)dF_\varepsilon \right] + o(h).
\]

Since

\[
\frac{\partial}{\partial \varepsilon} \Phi(F_\varepsilon) = \lim_{h \to 0} \frac{\Phi(F_{\varepsilon + h}) - \Phi(F_\varepsilon)}{h},
\]

using \( F_\varepsilon = \alpha F + (1 - \alpha)[\varepsilon F^* + (1 - \varepsilon)G_{\mu_F}] \), we find

\[
\frac{\partial}{\partial \varepsilon} \Phi(F_\varepsilon) = \lim_{h \to 0} \frac{1}{h} \left[ h(1 - \alpha) \left( \int U(x; F_\varepsilon)dF^* - U(\mu_{F^*}; F_\varepsilon) \right) \right]
\]

i.e.,

\[
\frac{\partial}{\partial \varepsilon} \Phi(F_\varepsilon) = (1 - \alpha) \left( \int U(x; F_\varepsilon)dF^* - U(\mu_{F^*}; F_\varepsilon) \right) \leq 0
\]

since \( U(\cdot, F_\varepsilon) \) is a concave function. Hence, we obtain that \( \Phi(F_0) \geq \Phi(F_1) \), i.e.,

\[
\Phi(\alpha F + (1 - \alpha)F^*) \geq \Phi(\alpha F + (1 - \alpha)G_{\mu_F^*}).
\]

Q.E.D.

(iii) \implies (ii) Consider a lottery as in Equation 2.1 such that

\[
\Phi(\alpha F + (1 - \alpha)G_{\mu_F^*}) \geq \Phi(\alpha F^* + (1 - \alpha)F^*).
\]

If \( \alpha \to 0 \), we obtain

\[
\left[ \int U(x; F)dG_{\mu_F^*} - \int U(x; F)dF \right] + o(1) \geq \left[ \int U(x; F)dF^* - \int U(x; F)dF \right] + o(1)
\]

which implies that

\[
\int U(x; F)dG_{\mu_F^*} - \int U(x; F)dF \geq \int U(x; F)dF^* - \int U(x; F)dF
\]

i.e.,

\[
\int U(x; F)dG_{\mu_F^*} \geq \int U(x; F)dF^*.
\]
i.e.,

\[ U(\mu_F^*; F) \geq \int U(x; F)dF^* \]

Hence, \( U(\cdot; F) \) is a convex function. \( \square \)

Using the local utility, we can define a full insurance premium for preferences over multivariate prospects. Let \( X \in \mathbb{D} \) be a prospect evaluated by a decision maker with smooth preferences as \( \Phi(X) \). A full insurance premium can be defined as an element of the set of vectors \( \pi \in \mathbb{R}^d \) satisfying \( \Phi(X) = U(\mathbb{E}X - \pi; F_X) \), where \( F_X \) is the distribution function of the random vector \( X \).

3. Increasing risk aversion in multivariate rank dependent utility

3.1. Aversion to monotone mean preserving increases in risk. In [21], Quiggin shows that the notion of mean preserving increases in risk is too weak to coherently order rank dependent utility maximizers according to increasing risk aversion. [21] shows that the notion of monotone mean preserving increases in risk (Monotone MPIR) is the weakest stochastic ordering that achieves a coherent ranking of risk aversion in the rank dependent utility framework. Monotone MPIR is the mean preserving version of Bickel-Lehmann dispersion ([2],[3]), which we now define.

**Definition 3** (Bickel-Lehmann Dispersion and Monotone Mean Preserving Increase in Risk). Let \( Q_X \) and \( Q_Y \) be the quantile functions of the random variables \( X \) and \( Y \). \( X \) is said to be Bickel-Lehmann less dispersed, denoted \( X \gtrsim_{BL} Y \), if \( Q_Y(u) - Q_X(u) \) is a nondecreasing function of \( u \) on \((0,1)\). The mean preserving version is called monotone mean preserving increase in risk (hereafter MMPIR) and denoted \( \gtrsim_{MMPIR} \).

MMPIR is a stronger ordering than MPIR in the sense that \( X \gtrsim_{MMPIR} Y \) implies \( X \gtrsim_{MPIR} Y \) since it is shown in [7] that an MPIR can be obtained as the limit of a sequence of simple mean preserving spreads \( Y \) of \( X \), defined by \( Q_Y(u) - Q_X(u) \) non-positive below some \( u_0 \in [0,1] \) and non-negative above \( u_0 \). [21] relates MMPIR aversion of a rank dependent utility decision maker to a notion he calls pessimism. Aversion to MMPIR is defined in the usual way as follows.
Definition 4. A preference functional $\Phi$ over random prospects is called averse to monotone mean preserving increases in risk if and only if $X \preceq_{\text{MMPIR}} Y$ implies $\Phi(X) \geq \Phi(Y)$.

Consider a decision maker with preference relation characterized by the functional defined for each prospect $X$ by

$$\Phi(X) = \int_{-\infty}^{\infty} f(1 - F_X(x)) dx$$

(3.1)

with $f(0) = 0$, $f(1) = 1$ and $f$ non decreasing. Then Theorem 3 of [6] shows that aversion to MMPIR is equivalent to $f(u) \leq u$ for each $u \in [0, 1]$. Since the local utility associated with $\Phi$ is $x \mapsto U_\Phi(x; F_X) = f(F_X(x))$, aversion to MMPIR can be characterized with the local utility. We now generalize this local utility characterization of MMPIR aversion beyond rank dependent utility functionals to all preference functionals that admit a local utility.

Theorem 2 (Local utility of MMPIR averse decision makers). Let $\Phi$ be a preference functional with local utility at $X$ denoted $x \mapsto U_\Phi(x; F_X)$. $\Phi$ is MMPIR averse if and only if

$$E\left[ \frac{U'(X; F_X)}{E[U''(X; F_X)]} 1\{X \leq x\} \right] \leq E[1\{X \leq x\}]$$

for all $X \in L^2$, almost all $x \in \mathbb{R}$.

Remark 1. Note that in the special case of rank dependent utility functional (3.1), the characterization above is equivalent to $f(F_X(x)) \leq F_X(x)$ for all $x$ and $X$, which is equivalent to $f(u) \leq u$ for all $u \in [0, 1]$ as mentioned previously.

In Proposition 2 of [17], Landsberger and Meilijson give a characterization of Bickel-Lehmann dispersion in the spirit of the characterization of MPIR given in the equivalence between (a) and (b) of Proposition 2.

Proposition 2 (Landsberger-Meilijson). A random variable $X$ has Bickel-Lehmann less dispersed distribution than a random variable $Y$ if and only if there exists $Z$ comonotonic with $X$ such that $Y \preceq_{d} X + Z$. 
Using Proposition 2, we can prove Theorem 2.

Proof of Theorem 2. From Proposition 2, $\Phi$ is MMPIR averse if and only if $\Phi(X + Z) - \Phi(X) \leq 0$ for any $(X, Z)$ comonotonic and $EZ = 0$. Now for $Z$ small enough,

$$\Phi(X + Z) - \Phi(X) = \int_0^1 U'_\Phi(Q_X(u); F_X)[Q_{X+Z}(u) - Q_X(u)]du$$

$$= \int_0^1 U'_\Phi(Q_X(u); F_X)Q_Z(u)du$$

since the quantile function is comonotonic additive. Therefore we have

$$\int_0^1 U'_\Phi(Q_X(u); F_X)Q_Z(u)du \leq 0$$

for any $Z$ with mean zero. After changing variables, this yields

$$\int_{-\infty}^{\infty} U'_\Phi(y; F_X)\Delta(y)dF_X(y)$$

for any function $\Delta$ increasing and such that $\int_{-\infty}^{\infty} \Delta(y)dF_X(y) = 0$. Choosing $\Delta(y) = 1\{y \leq x\} - F_X(x)$ yields the result. \qed

We now show how this notion of Bickel-Lehmann dispersion and the Landsberger-Meilijson characterization can be extended to multivariate prospects and how it can be applied to the ranking of risk aversion of multivariate rank dependent utility maximizers. To that end, we appeal to the multivariate notions of quantiles and comonotonicity developed in [10] and [8].

3.2. Multivariate quantiles and comonotonicity. [10] and [8] define multivariate quantiles by extending the variational characterization of univariate quantiles based on rearrangement inequalities of Hardy, Littlewood and Pólya [13]. The following well known equality

$$\int_0^1 Q_X(u)u du = \max \{E[X\tilde{U}] : \tilde{U} \text{ uniformly distributed on } [0, 1]\}, \quad (3.2)$$

is extended to the multivariate case to define the quantile $Q_X$ of a random vector $X \in \mathcal{D}$ with the following, where $\mu$ is a reference absolutely continuous distribution
on $\mathbb{R}^d$ with finite second moment.

$$\mathbb{E}[Q_X(U) \cdot U] = \max \left\{ \mathbb{E}[X \cdot \tilde{U}] : \tilde{U} \equiv_d \mu \right\}. \quad (3.3)$$

It follows from the theory of optimal transportation (see Theorem 2.12(ii), p. 66 of [30]) that there exists a convex lower semi-continuous function $V : \mathbb{R}^d \rightarrow \mathbb{R}$ such that $Q_X = \nabla V$ satisfies Equation 3.3. Hence the definition of multivariate quantiles due to [10] and [8].

**Definition 5 ($\mu$-quantile).** The $\mu$-quantile function of a random vector $X$ in $\mathcal{D}$ with respect to an absolutely continuous distribution $\mu$ on $\mathbb{R}^d$ is defined by $Q_X$ in Equation 3.3.

This concept of a multivariate quantile is the counterpart of the definition of multivariate comonotonicity in [10] and [8], motivated by the fact that two univariate prospects $X$ and $Y$ are comonotonic if there is a prospect $U$ and non-decreasing maps $T_X$ and $T_Y$ such that $Y = T_Y(U)$ and $X = T_X(U)$ almost surely or, equivalently, $\mathbb{E}[UX] = \max \left\{ \mathbb{E}[\tilde{U}X] : \tilde{U} =_d U \right\}$ and $\mathbb{E}[UY] = \max \left\{ \mathbb{E}[\tilde{U}Y] : \tilde{U} =_d U \right\}$.

**Definition 6 ($\mu$-comonotonicity).** Random vectors $X$ and $Y$ in $\mathcal{D}$ are called $\mu$-comonotonic if there exists $U =_d \mu$ such that $\mathbb{E}[X \cdot U] = \max \left\{ \mathbb{E}[\tilde{X} \cdot U] : \tilde{X} =_d X \right\}$ and $\mathbb{E}[Y \cdot U] = \max \left\{ \mathbb{E}[\tilde{Y} \cdot U] : \tilde{Y} =_d Y \right\}$.

Two random vectors are $\mu$-comonotonic if they can be rearranged simultaneously so that they are both equal to their $\mu$-quantile. Another variation notion of multivariate comonotonicity, called $c$-comonotonicity, is proposed in [20].

**Definition 7 ($c$-comonotonicity).** Random vectors $X$ and $Y$ in $\mathcal{D}$ are called $c$-comonotonic if there exists a convex function $V$ such that $Y = \nabla V(X)$.

Both $\mu$-comonotonicity and $c$-comonotonicity will feature in the extension of Bickel-Lehmann dispersion in the following section.
3.3. **Multivariate Bickel-Lehmann dispersion.** The Bickel-Lehmann dispersion order and its mean-preserving version in [21], monotone MPIR, rely on the notion of monotone single crossings, hence on the monotonicity of the function $Q_Y - Q_X$. A natural extension of the class of non-decreasing functions to functions on $\mathbb{R}^d$ is the class of gradients of convex functions, whose definition doesn’t rely on the ordering on the real line. Hence the following definition of $\mu$-Bickel-Lehmann dispersion, which depends on the baseline distribution $\mu$ relative to which multivariate quantiles are defined.

**Definition 8** ($\mu$-Bickel-Lehmann dispersion). A random vector $X \in \mathcal{D}$ is called $\mu$-Bickel-Lehmann less dispersed than a random vector $Y \in \mathcal{D}$, denoted $X \succeq_{\mu BL} Y$, if there exists a convex function $V : \mathbb{R}^d \to \mathbb{R}$ such that the $\mu$-quantiles $Q_X$ and $Q_Y$ of $X$ and $Y$ satisfy $Q_Y(u) - Q_X(u) = \nabla V(u)$ for $\mu$-almost all $u \in [0,1]^d$.

As defined above, $\mu$-Bickel-Lehmann dispersion defines a transitive binary relation, and therefore an order on $\mathcal{D}$. Indeed, if $X \succeq_{\mu BL} Y$ and $Y \succeq_{\mu BL} Z$, then $Q_Y(u) - Q_X(u) = \nabla V(u)$ and $Q_Z(u) - Q_Y(u) = \nabla W(u)$. Therefore, $Q_Z(u) - Q_X(u) = \nabla (V(u) + W(u))$ so that $X \succeq_{\mu BL} Z$. When $d = 1$, this definition simplifies to definition 3.

3.3.1. **Characterization.** We have the following generalization of the Landsberger-Meilijson characterization of Proposition 2.

**Theorem 3.** A random vector $X \in \mathcal{D}$ is $\mu$-Bickel-Lehmann less dispersed than a random vector $Y \in \mathcal{D}$ if and only if there exists a random vector $Z \in \mathcal{D}$ such that (i) $X$ and $Z$ are $\mu$-comonotonic and (ii) $Y =_d X + Z$.

**Proof of Theorem 3.** Assume $X \succeq_{\mu BL} Y$ and call $Q_X$ and $Q_Y$ the $\mu$-quantiles of $X$ and $Y$. Let $U$ be a random vector with distribution $\mu$ such that $X = Q_X(U)$. By assumption, $\nabla V(U)$ is equal to $Q_Y(U) - Q_X(U) = Q_Y(U) - X$. Call $Z = \nabla V(U)$. By Theorem 2.12(ii), p. 66 of [30], $\nabla V$ is the $\mu$-quantile $Q_Z$ of $Z$. Hence we have $X = Q_X(U)$ and $Z = Q_Z(U)$ and $X$ and $Z$ are therefore $\mu$-comonotonic and we have $Y =_d Q_Y(U) = X + Z$ as required. Conversely, take $X$ and $Z$ $\mu$-comonotonic. Then
\[ X = Q_X(U) \text{ and } Z = Q_Z(U) \] for some \( U = \mu \), where \( Q_X \) and \( Q_Z \) are the \( \mu \)-quantiles of \( X \) and \( Z \) respectively. Call \( Y = X + Z \) and \( Q_Y = Q_{X+Z} \) the \( \mu \)-quantile of \( Y \). In the proof of Theorem 1 of \([10]\), it is shown that \( Q_{X+Z} = Q_X + Q_Z \) when \( X \) and \( Z \) are \( \mu \)-comonotonic. Hence, we have \( Q_Y = Q_X + Q_Z \), i.e., \( Q_Y - Q_X = Q_Z \), and \( Q_Z \) is the gradient of a convex function by Definition 5. The result follows.

The characterization given in Theorem 3 now allows us to generalize our characterization of MMPIR aversion to the multivariate case.

**Proposition 3** (Local utility of multivariate MMPIR averse decision makers). A decision functional \( \Phi \) is \( \mu \)-MMPIR averse if and only if its local utility function satisfies

\[
E_\mu [\nabla V(U) \cdot \nabla U(\nabla V_X(U); F_X)] \leq 0
\]

for all \( V \) convex with \( E_\mu V(U) = 0 \).

**Proof of Proposition 3.** Let \( Y \) dominate \( X \) with respect to mean preserving \( \mu \)-Bickel-Lehmann dispersion, i.e., \( Y \gtrsim_{\mu-MMPIR} X \). This is equivalent to \( Y = d X + Z \) with \( X \) and \( Z \) \( \mu \)-comonotonic, \( E Z = 0 \). For each \( \epsilon > 0 \), define \( Y_\epsilon = X + \epsilon Z \), which also dominates \( X \) with respect to \( \mu \)-Bickel-Lehmann dispersion. \( \Phi \) is \( \mu \)-MMPIR averse if and only if for all \( \epsilon > 0 \), \( \Phi(X + \epsilon Z) - \Phi(X) \leq 0 \). Denoting \( Q_{X+\epsilon Z} \) and \( Q_X \) the \( \mu \)-quantiles of \( Y_\epsilon \) and \( X \) respectively and \( U = d \mu \), comonotonicity of \( X \) and \( Z \) implies \( Q_{Y_\epsilon}(U) = Q_{X+\epsilon Z}(U) = Q_X(U) + \epsilon Q_Z(U) \). Hence,

\[
0 \geq \Phi(X + \epsilon Z) - \Phi(X) = E U_\Phi(X + \epsilon Z; F_X) - E U_\Phi(X; F_X) = E U_\Phi(Q_{X+\epsilon Z}(U); F_X) - E U_\Phi(Q_X(U); F_X) = E [\epsilon Q_Z(U) \cdot \nabla U_\Phi(Q_X(U); F_X)] + o(\epsilon). \]

Hence, \( E [\epsilon Q_Z(U) \cdot \nabla U_\Phi(Q_X(U); F_X)] \leq 0 \), which completes the proof.

The characterization given in Theorem 3 is also crucial to the results in the next section on comparative risk attitudes of multivariate rank dependent utility maximizers. A simple corollary of the characterization given in Theorem 3 is that, as in the univariate case, the mean preserving version of \( \mu \)-Bickel-Lehmann dispersion is a stronger order than the order of MPIR in the sense of the following.
Corollary 1. Given a reference distribution $\mu$ and two multivariate prospects $X,Y \in \mathcal{D}$ with identical means, $X \succsim_{\mu \text{-BL}} Y$ implies $X \succsim_{\text{MPIR}} Y$.

The proof is immediate, as the characterization of $\mu$-Bickel-Lehmann dispersion in Theorem 3 implies the martingale characterization (b) of MPIR in Definition 2.

3.3.2. Relation to other multivariate dispersion orders. Two generalizations of Bickel-Lehmann dispersion were proposed in the statistical literature. Strong dispersion proposed by [11] and Rosenblatt dispersion proposed by [27].

Definition 9 (Strong dispersive order). $Y$ is said to dominate $X$ in the strong dispersive order, denoted $Y \succsim_{SD} X$ if $Y =_d \phi(X)$, where $\phi$ is an expansion, i.e., such that $||\phi(x) - \phi(x')|| \geq ||x - x'||$ for all pairs $(x, x')$.

The following Proposition gives conditions under which $\mu$-Bickel-Lehmann is equivalent to [11]'s strong dispersion.

Proposition 4. Let $X$ and $Y$ be two random vectors in $\mathcal{D}$. The following propositions hold.

1. $Y$ is also more dispersed than $X$ in the strong dispersion order, i.e., $Y \succsim_{SD} X$, if and only if $Y =_d X + Z$, where $X$ and $Z$ are $c$-comonotonic.
2. If $Y \succsim_{SD} X$, then there exists $\mu$ such that $Y \succsim_{\mu \text{-BL}} X$.
3. If $Y \succsim_{\mu \text{-BL}} X$ and the $\mu$-quantiles of $X$ and $Y$ are gradients of strictly convex functions, then $Y \succsim_{SD} X$.

Proof of Proposition 4. Proof of 1.: Follows from the characterization of the strong dispersive order in Theorem 2 of [11] and the fact that the Jacobian $J_{\nabla V}$ of $\nabla V$ is positive semi-definite if and only if $V$ is convex. Proof of 2.: This follows immediately from the proof of 1., taking $\mu$ equal to the distribution of $X$. Proof of 3.: If $Y \succsim_{\mu \text{-BL}} X$, then by Theorem 3, $Y =_d X + Z$, where $X$ and $Z$ are $\mu$-comonotonic. Hence

$$Y =_d Q_{X+Z}(U) = Q_X(U) + Q_Z(U) =_d X + Q_Z(Q_X^{-1}(X)),$$
where \( Q_X = \nabla V_X \) and \( Q_Z = \nabla V_Z \) are gradients of convex functions. Therefore, denoting \( \phi(x) = x + \psi(x) = x + \nabla V_Z \circ (\nabla V_X)^{-1}(x) \), we need to show that \( \phi \) satisfies the \( J^{T}_{\phi}(x)J_{\phi}(x) - I \geq 0 \) for all \( x \) as in the characterization of the strong dispersive order in Theorem 2 of [11]. This follows from the fact that the jacobian of a gradient of a strictly convex function is positive definite and that

\[
J_{\psi}(x) = [J_{\nabla V_X}((\nabla V_X)^{-1}(x))]^{-1} [J_{\nabla V_Z}((\nabla V_X)^{-1}(x))] 
\]

is also positive definite. Note that the product of two semi-definite positive matrices is not necessarily positive semi definite. Hence, implication 3. does not necessarily hold without the strict convexity assumption. This is related to the fact that \( \mu \)-comonotonicity of \( X \) and \( Z \) does not always imply \( c \)-comonotonicity, as the composition of two gradients of convex functions is not necessarily the gradient of a convex function.

The dispersion order that we dubbed Rosenblatt dispersion, proposed by [27] is based on the classical Lévy-Rosenblatt quantiles.

**Definition 10 (Lévy-Rosenblatt quantiles).** The Lévy-Rosenblatt transform is defined for each \( u = (u_1, \ldots, u_n) \) in \([0, 1]^n\) by

\[
R_X(u) = (R_1(u_1), R_2(u_1, u_2), \ldots, R_n(u_1, \ldots, u_n),
\]

with

\[
R_1(u_1) = Q_{X_1}(u_1)
\]

\[
R_i(u_1, \ldots, u_i) = Q_{X_i|X_1=R_1(u_1),\ldots,X_{i-1}=R_{i-1}(u_1,\ldots,u_{i-1})}(u_i), \text{ for each } 1 < i \leq n.
\]

In direct analogy with Definition 3, the Rosenblatt dispersive order is defined through monotonicity of the difference in Lévy-Rosenblatt quantiles.

**Definition 11 (Rosenblatt dispersive order).** \( Y \) is more dispersed than \( X \) according to the Rosenblatt dispersive order, denoted \( Y \succsim_{RD} X \), if \( R_Y(u') - R_X(u') \geq R_Y(u) - \)
$R_X(u)$ (componentwise) when $u' \geq u$ (componentwise) and $R_X$ and $R_Y$ denote the Rosenblatt transforms of $X$ and $Y$.

[5] characterize the link between Lévy-Rosenblatt quantiles of Definition 10 and $\mu$-quantiles of Definition 5. Take $\mu$ equal to the uniform on $[0, 1]^n$. Let $U =_{d} \mu$. Then $\mu$ quantiles satisfy

$$\mathbb{E}(Q_X(U) - U)^2 = \min_{\tilde{X} =_{d} X} \mathbb{E}(\tilde{X} - U)^2.$$ 

[5] show that Rosenblatt quantiles are obtained as a limit of $R_X^\varepsilon$ quantile maps such that:

$$\mathbb{E}[\lambda^\varepsilon \cdot (R_X^\varepsilon(U) - U)^2] = \min_{\tilde{X} =_{d} X} \mathbb{E}[\lambda^\varepsilon \cdot (\tilde{X} - U)^2],$$

with $\lambda^\varepsilon = (\lambda_1^\varepsilon, \ldots, \lambda_n^\varepsilon)$ when $\lambda_k^\varepsilon/\lambda_{k-1}^\varepsilon \to 0$ for all $1 < k \leq n$ as $\varepsilon \to 0$.

Note that the above generalizations of the Bickel-Lehmann dispersive ordering does not preserve the comonotonicity characterization of Proposition 2 as our proposal in Definition 8 does.

3.4. Increasing risk aversion and multivariate rank dependent utility. To make interpersonal comparisons of attitudes to multivariate risk, we define compensated increases in risk in the spirit of [7].

**Definition 12** (Compensated Increases in Risk). Let $\Phi$ be the functional representing a decision maker’s preferences over multivariate prospects in $\mathcal{D}$. A prospect $Y \in \mathcal{D}$ is a compensated increase in risk from the point of view of $\Phi$ is $X \succeq_{\mu BL} Y$ and $\Phi(Y) = \Phi(X)$.

A ranking of risk aversion is then derived in the usual way, except that the ranking of aversion to multivariate risks is predicated on the reference measure $\mu$ in the definition of dispersion.

**Definition 13** (Increasing risk aversion). A decision maker $\tilde{\Phi}$ is more risk averse than a decision maker $\Phi$ if $\tilde{\Phi}$ is averse to a compensated increase in risk from the point of view of $\Phi$, i.e., if $X \succeq_{\mu BL} Y$ and $\Phi(Y) = \Phi(X)$ imply $\tilde{\Phi}(Y) \leq \tilde{\Phi}(X)$. 
In the special case of rank dependent utility maximizers, aversion to monotone MPIR and increasing risk aversion take a very simple form. We consider here the multivariate generalization of Yaari decision makers given in [10]. A multivariate rank dependent utility maximizer is characterized by a functional $\Phi$ on multivariate prospects $X \in \mathcal{D}$, which is a weighted sum of $\mu$-quantiles, i.e.,

$$
\Phi(X) = \mathbb{E}[Q_X(U) \cdot \phi(U)],
$$

where $Q_X$ is the $\mu$-quantile of $X$, $U =_d \mu$ and $\phi(U) \in \mathcal{D}$. As shown in Theorem 1 of [10], $\Phi(X + Z) = \Phi(X) + \Phi(Z)$ when $X$ and $Z$ are $\mu$-comonotonic. Hence we immediately find the following characterization of monotone MPIR aversion and increasing risk aversion.

**Theorem 4 (Rank dependent utility).** Let $\Phi$ and $\tilde{\Phi}$ be multivariate rank dependent utility functionals, i.e., $\Phi$ and $\tilde{\Phi}$ satisfy (3.4). Then the following hold.

(a) $\Phi$ is averse to a monotone MPIR (i.e., a mean preserving $\mu$-Bickel-Lehmann dispersion) if and only if for all $Z \in \mathcal{D}$, $\Phi(Z) \leq \Phi(\mathbb{E}Z)$.

(b) $\tilde{\Phi}$ is more risk averse than $\Phi$ if and only if for all $Z \in \mathcal{D}$, $\Phi(Z) = 0 \Rightarrow \tilde{\Phi}(Z) \leq 0$.

It turns out, therefore, that aversion to MMPIR in the multivariate rank dependent utility model is equivalent to weak risk aversion. Yaari’s rank dependent utility maximizers over stochastically independent multivariate risks in [31] are special cases of (3.4) where the reference distribution $\mu$ has independent marginals. In that special case, (a) of Theorem 4 is equivalent to concavity of the local utility function in (1.2) (i.e., non-increasing $\phi_i$ for each $i$) and (b) of Theorem 4 is equivalent to $\tilde{\phi}_i$ being a decreasing transformation of $\phi_i$ for each $i$, so that we recover the classical results of [31].

**Conclusion**

Attitudes to multivariate risks were characterized using Machina’s local utility in a framework, where objects of choice are multidimensional prospects. Aversion to mean
preserving increases in multivariate risk is characterized by concavity of the local utility function as in the univariate case. Comparative attitudes are characterized within the multivariate extension in [10] of rank dependent utility with the help of a multivariate extension of Quiggin’s monotone mean preserving increase in risk notion and a generalization of its characterization in [17]. Characterization and derivation of risk premia within the multivariate rank dependent utility model is the natural next step in this research agenda.
